

Linux Distributions

There are many different Linux distributions that people use. The one I use is Ubuntu, I use Ubuntu because it appeals to me the most out of the other ones that they have. Some of the tools that Ubuntu offers is Libre Office Writer, which is like Microsoft Word, or google docs. This tool is useful because you can use it to type whatever you want like papers and essays that were assigned to you from school. The latest version is Ubuntu 20.04 code named Focal Fossa. It provides numerous improvements and new features such as the new Yaru theme, new look and polished icons. This is good because having improvements a lot and features is what keeps a distribution up to date, and patches bugs that are found. Maybe other distributions might not update as much so many bugs accumulate and can lead to a lot of issues. Another distribution for Linux is Debian, Debian is renowned for being a mother to popular Linux distributions such as Deepin, Ubuntu, and Mint which have provided solid performance, stability, and unparalleled user experience. Debian provides over 59,000 software packages and supports a wide range of PCs with each release encompassing a broader array of system architectures. It strives to strike a balance between cutting edge technology and stability. Debian provides 3 salient development branches: Stable, Testing, and Unstable. The difference between the two is that Ubuntu releases updates with the same name, whereas in Debian once it releases a new version of it you can download it before it releases and it comes with different names, one new version that is in development is called Bullseye.
